

Development Environment

All components of the Wordpress platform and the front-end website, are hosted on Amazon Web Services (AWS), which provides multiple redundancy, 24/7 virus and intrusion detection, server patching, and IT maintenance. Additionally, our IT team provides 24/7 end-user support for connectivity or data issues.

For Setup:

1. Celerate's IT establishes development environments
 - a. **Stage (stage-website.n4m.net):** This environment is used for testing and staging content for production
 - b. **Production (prod-website.n4m.net):** This is the production environment where we do all final testing and approvals once the site is approved for go live we then move over the DNS and once that propagates the site will go live.
2. Before go live, we will move the site domain name to Celerate's registrar to set up the server's load balancer.
3. The client will provide any email addresses that will be used to send and receive emails on site. Those will be approved and registered with AWS ensuring that they do not get blacklisted with email servers.
